Short Research Paper

The Future under Global Warming

1. Introduction

The world economy and global warming has a strong relationship in energy. Energy is vital for large scale economic output and energy results in green house gases when fossil fuels are burnt. Thus, when energy supply must be transformed to renewables then what are the economic consequences. Or if the world does face Hawking irreversibility, can fossil fuel energy be cut back without economic recession?

Energy is the capacity to do work, thus extremely valuable to human beings and societies. Its use is essential in economic affairs as well as in politics and military matters. Energy consumption has virtually exploded after WWII, but it has a drawback in the form of greenhouse gases. Planet Earth wants ever more energy, but it should fear climate change. This conflict will most likely run through this entire century, however it may be resolved.

Germany started the Second World War, ending up fighting in the West, North, East and South. Hitler lost gruesomely as he lacked a secure supply of energy for the war machine. In his craze, he sent soldiers to Baku in order to capture Soviet oil, splitting his forces. How could the United States of present times exercise military dominance in the world without energy for its 20 aircraft carriers? It is even capable of bombing Iran using launching grounds like Diego Garcia or even Fairbanks, Alaska.

Countries place great emphasis on secure access to affordable energy from internal or external sources. This poses great challenges, for instance Japan and Germany have supply problems due to the closing of nuclear reactors.

2. Future Economic Activity

Under rational expectations, the market players search for the most recent information around the globe. They update their beliefs continuously with consequences for the development of strategies. Since the global stock markets have been rising even after Greta Thunberg warned us of the negative ramifications of global warming, one may conclude that the markets either neglect climate change or believe that economic activity can successfully adapt. It was not until this week in January 2020 that the CEO of the largest investment fund (Black Rock) announced to a surprised audience that financial economics must take into account what global warming implies for the real economy. Financial economics is not only about rational expectations, it also involves speculation and overshooting. The risk for economic recession is clearly obvious as market players may find it difficult to support sustainable companies that can survive and thrive under climate change.

I would argue that the capacity of global markets to respond to the real economic consequences of climate change is unclear. A successful response from the market economy requires much more than what has been presented hitherto. I would also be inclined to argue that the alternative to market adaptation, i.e., the creation of an international common pool regime is not going to be effective. United Nations efforts (e.g., the COP framework) have been going on for a long time without concrete results. The failing of international bargaining can be explained by means of game theory. Modeling the Common Pool Regime (CPR) as a giant Prisoners Dilemma (PD) game, running over several years of rounds. It involves too many conflicts over the access to energy, both regarding production and distribution. If world political leaders took the UN negotiations seriously, then they would start by eliminating coal-fired power plants before anything else, through financial schemes.

Below we make an attempt to calculate how much solar energy would be required to replace coal power. As benchmark the Bhadla Solar Park in India is used, projected to deliver 2255 MW once construction is ready from December 2019. In all, 900 such plants would be necessary to completely eliminate all coal power generated in 2018. Table I illustrates how many solar plants of this size each of the ten biggest coal producing nations would need to install to replace their entire coal power production.

Country	Number of plants
China	475
India	100
Japan	28
South Korea	18
Turkey	9
Americas	
United States	106
Colombia	1
Europe:	
Germany	32
Russia	30

Damocles Sword

The global energy / environment problematic contains three factors:

- a) Energy Consumption (unit: billion tonnes of oil equivalent)
- b) CO2 Atmospheric Concentration (unit: ppm)
- c) Global Temperature Anomaly (unit: Degrees Centigrade)

At present, we stand at almost 16 billion tonnes of oil equivalent in annual world production, which has led to a near one degree rise in global temperatures. The future holds the scenarios presented in Table 2.

Global Energy / btoe	CO2 concentration / PPM	Temperature rise / degrees C
16	430	1.1
18	450	1.3
20	470	1.5
22	490	1.7
24	510	2.0

Table 2. Regression Estimates for Temperature Rise Based on Energy Consumption

In Table 2 the relationship between energy consumption and temperature rise is modelled. Energy consumption is near 16 billion with + 1 degree. Looking at stylised projections, we will move towards 24 billion with + 2 degrees. That would create lots of difficult problems for mankind.

It follows from Table 2 that if energy consumption keeps rising according to predictions, we will soon reach +2 degrees. Any further increase in energy consumption will release the Damocles sword of higher temperature rises. Can mankind survive +3 or +4 degrees?
